Some Definitions and Advice about Pollination and Seed Collecting.

by: Gert Forum Petersen

Voerlose Denmark

Pollination: The transfer of the male pollen to the female stigma in order to obtain fertile seeds.

Siblings: Plants of the same parental origin.

Intra -siblings: Cross among siblings.

Inter-clonal: Cross between to different clones of the same species.

Selfed: Pollination with the flower's own pollen or pollen from another plant from the same clone;

many leptode and some elipidote Rhododendrons are self-fertile but in any case cross pollination of species produces more vigorous offspring.

C.W. = Collected Wild: I.e. seeds harvested from wild plants at their natural habitat. The seeds coming true will mainly look like the mother, but hybrids can occur. Besides the name of the species the geographic location and the altitude is important information.

O.P. = Open Pollination: The pollination has happened in the natural way by the aid of insects, birds, wind or self pollination, perhaps before the flower has opened. Under garden conditions, where many species- (seperated in nature)- grow close together, the majority of the open pollinated seeds will be hybrids with unknown father(s) and the value of the offspring will be unpredictable. With species which are known not to hybridize: *R. albiflorum*, *R. camtschaticum*, *R. schlippenbachii*, *R. semibarbatum* and *R. vaseyi*, open pollinated seeds can be compared to C.P. seeds except for the fact that mix of color can occur.

H.P. = Hand Pollination: Emasculation, i.e. the removal of the corolla and stamens from the unopened flower, leaves the style with the untouched stigma unattractive to insects, with a remarkable

1992 increase of the risk for unwanted pollination -

without totally eliminating the risk of it. The pollination is carried out "by hand" by placing pollen from the selected father on the stigma. No effort is made to protect the stigma either before or after the pollination - but at least the nearby neighbouring flowers should be removed.

C. P. = Controlled Pollination: Gives you full control over the entire pollination process: The clean stigma from the unopened flower is pollinated as for H.P. and the stigma is then protected against unwanted pollen with micropore tape or easier by means of a little aluminum foil tube. If the stigma is not ready (shining and sticky) for receiving the pollen (particularly important when using frozen pollen), the stigma must be protected until ready; best of all with an aluminum foil tube which can easily be removed without harming the stigma. With C.P. it is often unnecessary to remove corolla and stamens. The omission of this process lowers the risk of self pollination.

Collecting seed capsules and extracting seeds.

1. Collect capsules when ripe, i.e. when it changes from greenish to brown in the top at least, but before it opens. Otherwise many seeds can be lost and the remaining seeds will often be contaminated with fungus spore. Unripe capsules can be used, but the lasting quality of the seeds will be somewhat reduced.

2. After storing the capsules in an open container or paper envelope for a week or so in a warm (20 or 30C = 68 to 86F) and dry place, it will open and release the seeds. If not, open (split) the capsule with a nail or knife- but gently: The Ericaceae seeds are mechanically weak, unfortunately. Splitting is often necessary for deciduous azaleas whose capsules require frost before opening naturally, and for small lepidodes capsules.

3. Shake the capsules to get the seed out, help gently, perhaps with a needle.

4. Clean the seeds well; different sizes of sieves are very helpful when separating bits of capsule, barren seeds and viable seeds and /or let the seeds roll several times down a stiff piece of paper by tapping with a finger: The waste will stick more to the paper than the good seeds.

5. Store the seeds cold (5-8C = 41-48F) best in a closed glass jar with moisture absorbing silicagel (changes from blue to rose when worn out, and can be regenerated many times by heating). The germination ability will be prolonged dramatically by

cold and dry storage.

6. If the seeds have to be mailed, they must be protected by bubble plastic or the like to prevent crushing when passing through the modern mail distributing machines. Rhododendron seeds are unfortunately mechanically weak seeds.*****

NOTE: Abbreviation and definition by: Dr. Mossman & Mike McCullough

SM: Smith-Mossman

SMO:Smith-Mossman-Oliver

HS:Howard Slonecker

SM30:A clone of R. occidentale with orange flare on every petal

HS5=a: similar to SM30

SM502like:a clone of R. occidentale with broad red/violet colored picotee band around all petal margins

SM502lite:similar to 502like

SM2406:a clone of R. occidentale with red/violet flowers.

SM189:a clone of R. occidentale with 4" diameter flowers

SM28-2:a clone of R. occidentale with 12 to 15 petals per corolla.

SM36:a clone of R. occidentale with many extra petals and late bloomer.

SM56:a clone of R. occidentale, always a late bloomer.

(SM189 x SM232):a clone of R. occidentale in-traspecific cross of R. occidentale with large frilled flowers.

R. calendulaceum var. 'Colossus': a clone found by August Kehr and David Leach. Late bloom with 4" scarlet flowers.

R. prunifolium: scarlet flowers and always blooms in late July and August in spite of hot sun.

R. viscosum:a fragrant white late bloomer.

SM231:R. occidentale, another picotee

R. macrophyllum var. 'Albion Ridge':a pure white flower with frilled petal margins.

GG:Gene German

GG4aK:Allan Korth

TT:Tom Tatem

81#3: variegated foliage

Location area before #: Mike McCullough

Bud Richards: Noted for his deciduous azalea hybrids that bloom 2 to 3 years from seed.

Queen Grex and Princess Grex: both hybridized by Jerry Harris, and produce large multi flowers per
